

ABSTRACT OF THE DISCLOSURE

A bus system and a command delivering method includes (a) delivering a first command to a first slave device, and (b) delivering a second command to a second slave device at a point in time which is less than or equal to a latency time of the second slave device in advance of the completion of data transfer according to the first command.

5 Accordingly, preparation necessary for data transfer can begin sooner, thereby reducing idle clock cycles of a data bus.
